IMPORTANT REMINDER

This Clinical Policy has been developed by appropriately experienced and licensed health care professionals based on a thorough review and consideration of generally accepted standards of medical practice, peer-reviewed medical literature, government agency/program approval status, and other indicia of medical necessity.

The purpose of this Clinical Policy is to provide a guide to medical necessity. Benefit determinations should be based in all cases on the applicable contract provisions governing plan benefits (“Benefit Plan Contract”) and applicable state and federal requirements including Local Coverage Determinations (LCDs), as well as applicable plan-level administrative policies and procedures. To the extent there are any conflicts between this Clinical Policy and the Benefit Plan Contract provisions, the Benefit Plan Contract provisions will control.

Clinical policies are intended to be reflective of current scientific research and clinical thinking. This Clinical Policy is not intended to dictate to providers how to practice medicine, nor does it constitute a contract or guarantee regarding results. Providers are expected to exercise professional medical judgment in providing the most appropriate care, and are solely responsible for the medical advice and treatment of members.

SUBJECT:

Medical necessity determination of fundus photography.

DESCRIPTION:

Fundus photography involves the use of a retinal camera to photograph regions of the vitreous, retina, choroid, and optic nerve. The resultant images may be either photographic or digital and become part of the patient’s permanent record. Fundus photographs are usually taken through a dilated pupil in order to enhance the quality of the photographic record, unless unnecessary for image acquisition or clinically contraindicated.

Fundus photography should be employed only when photographic documentation is necessary to the ongoing management of the specific ocular disease process affecting the patient. Most ophthalmic disorders may be managed very efficiently without the use of frequent photo documentation. Fundus photography is seldom of value in cases of minimal diabetic retinopathy or when diabetic retinopathy is unchanged from the previous photographic appearance.

Fundus autofluorescence (FAF) is a non-invasive retinal imaging modality used in clinical practice to provide a density map of lipofuscin, the predominant ocular fluorophore, in the retinal pigment epithelium. Multiple commercially available imaging systems, including the fundus camera, the confocal scanning laser ophthalmoscope, and the ultra-widfield imaging device, are available to the clinician. The fundus camera is a digital system that captures autofluorescence using a single flash of light. To reduce autofluorescence of the lens and cornea, Spaide introduced the ‘modified Topcon’ filter set with red-shifted wavelengths, with an excitation spectra of 535–585 and a 615–715 nm emission barrier filter. The use of the red-shifted wavelengths by fundus cameras decreases absorption by macular pigments, allowing detection of subtle perifoveal RPE changes. This excitation spectra also decreases absorption by the crystalline lens, preserving image quality in cases of cataract. Confocal scanning laser ophthalmoscope (cSLO) systems utilize a system of mirrors to focus a low power laser in a two-dimensional raster pattern onto the fundus. Platforms use a blue excitation wavelength of 488 nm and detect emission wavelengths of 500–700 nm. Confocal optics reduce light detection to a single optical plane, eliminating scattered light and interference from structures outside the retina, such as the crystalline lens. cSLO systems offer real-time averaging, where typically nine to sixteen images are averaged to produce high-contrast and high-resolution images.

POLICY/CRITERIA:

Fundus photography or fundus autofluorescence is performed in patients with histoplasmosis, choroidal neoplasms, glaucoma, diabetic retinopathy, hypertensive retinopathy, retinal neovascularization, macular pathology, and other visible retinal disorders that the ordering duly licensed eye care provider has determined requires

documentation. A fundus camera (or cSLO) is used to produce photographs of both retinas, and the duly licensed eye care provider interprets the results.

Fundus photography or similar scanning laser image shall not replace a thorough fundus exam through dilated pupils and shall not be used as a screening tool. Fundus photography is not a covered service when used to document the absence of pathology (i.e., a normal or healthy fundus or screening) or when the duly licensed eye care provider elects to incorporate it as a routine procedure.

Fundus photography or fundus autofluorescence is covered once annually (service date to service date) when medically indicated and documented in accordance with this policy. The medical record must clearly indicate the reason for the diagnostic test and how it will aid in clinical decision-making. An interpretation and report must be included as a permanent part of the medical record. When multiple diagnostic tests are performed, a separate interpretation and report must be completed for each test. The interpretation and report may be included with the encounter documentation; however, must be separate from an examination.

The interpretation and report of fundus photography or fundus autofluorescence must contain the following:

- Clinical findings – pertinent findings regarding the test results
- Comparative Data – comparison to previous test results (if applicable)
- Clinical Management – how the test results will affect management of the condition/disease
 - Change/increase/stop medication
 - Recommendation for surgery
 - Recommendation for further diagnostic testing
 - Referral to a specialist/sub-specialist for additional treatment

Medical records must be submitted with the claim in order for services that exceed frequency limitations to be considered for payment.

Fundus photography and autofluorescence subject to retrospective medical record review. The medical record must clearly indicate the reason for the diagnostic test and how it will aid in clinical decision-making.

Professional services provided by duly licensed eye care providers must be within the scope of licensure as defined by applicable State guidelines.

SCIENTIFIC BACKGROUND:

The optical design of fundus cameras is based on the principle of monocular indirect ophthalmoscopy. A fundus camera provides an upright, magnified view of the fundus. A typical camera views 30 to 50° of retinal area, with a magnification of 2.5x, and allows some modification of this relationship through zoom or auxiliary lenses from 15°, which provides 5x magnification, to 140° with a wide angle lens, which minifies the image by half. The optics of a fundus camera are similar to those of an indirect ophthalmoscope in that the observation and illumination systems follow dissimilar paths. The observation light is focused via a series of lenses through a doughnut shaped aperture, which then passes through a central aperture to form an annulus, before passing through the camera objective lens and through the cornea onto the retina. The light reflected from the retina passes through the un-illuminated hole in the doughnut formed by the illumination system. As the light paths of the two systems are independent, there are minimal reflections of the light source captured in the formed image. The image forming rays continue towards the low powered telescopic eyepiece. When the button is pressed to take a picture, a mirror interrupts the path of the illumination system allow the light from the flash bulb to pass into the eye. Simultaneously, a mirror falls in front of the observation telescope, which redirects the light onto the capturing medium, whether it is film or a digital CCD. Because of the eye's tendency to accommodate while looking through a telescope, it is imperative that the exiting vergence is parallel in order for an in-focus image to be formed on the capturing medium.¹

In fundus autofluorescence, autofluorescent patterns result from the complex interaction of fluorophores such as lipofuscin, which release an autofluorescent signal, and elements such as melanin and rhodopsin, which absorb the excitation beam and attenuate autofluorescence. Other structures such as retinal vessels and the crystalline lens may also influence autofluorescence through blocking and interference. Spatial variations in normal background autofluorescence reflect the distribution of lipofuscin and other fluorophores, which in turn reflect the distribution of photoreceptors and RPE cells. Meanwhile, the overall intensity of the autofluorescent signal is determined by individual factors such as age, light exposure, genotype, etc.

A large portion of hyper-autofluorescent lesions results from alterations in lipofuscin metabolism. Accumulation of lipofuscin in RPE cells, accumulation of bisretinoids in photoreceptor outer segments, and photooxidation of bisretinoids in lipofuscin can all contribute to enhanced autofluorescence. Specific mechanisms vary by disease, ranging from the inability to clear bisretinoids from photoreceptor cells in Stargardt disease to superimposed RPE cells in geographic atrophy (GA) of age-related macular degeneration (AMD). Accumulation of subretinal vitelliform material in Best disease, adult onset vitelliform maculopathy, and other acquired vitelliform disorders is another classic etiology of hyper-autofluorescence. Hyper-autofluorescence can also result from a window defect due to loss of rhodopsin, which normally absorbs the excitation wavelength and decreases autofluorescence. Rhodopsin attenuation and hyper-autofluorescence can occur physiologically as seen in the bleaching effect. In disease, photoreceptor degeneration and loss of rhodopsin unmasks the autofluorescent signal of the underlying RPE, creating hyper-autofluorescent lesions such as in white dot syndromes and other pathologies. Fluorophores other than lipofuscin, including optic disc drusen, can also form hyper-autofluorescent lesions.

In contrast, hypo-autofluorescence can arise from decreased lipofuscin or blockage by material anterior to the RPE/photoreceptors. Perhaps the most striking example of hypo-autofluorescence due to decreased lipofuscin is the absence of autofluorescence at the site of RPE tears, where the RPE is completely denuded. Other pathologies involving decreased lipofuscin include RPE atrophy in GA and

visual cycle defects in fundus albipunctatus. Meanwhile, blockage can occur from any material anterior to the RPE/photoreceptors, including physiologic structures such as blood vessels and macular pigments, and pathologic structures such as media opacities, intraretinal or subretinal hemorrhage, and fibrosis.

PRODUCT TYPE: All	COMMITTEE APPROVAL: 01/09/2018

same day, payment will be based on the reimbursement rate for a single code. No additional allowance will be paid if RT, LT, or modifier 50 is billed. If performed on one eye only, CPT code 92250 is submitted with modifier (52) and RT or LT, in order to indicate reduced services and the eye on which the imaging was taken.

Envolve Vision Benefits, Inc. (Envolve Vision) follows the National Correct Coding Initiative (CCI) guidelines when processing claims for these services. If the claim is denied based upon CCI edits, an appeal must be submitted with the medical records and a dictated and signed statement from the provider clearly stating what additional information will be gleaned by multiple imaging and how these multiple images will positively impact the patient's care.

Envolve Vision follows the Multiple Procedure Payment Reduction guidelines (MPPR) when reimbursing for multiple diagnostic procedures. CCI guidelines are applied prior to MPPR.
